

ABSTRACT

An authentication system that verifies various types of authenticity in regards with a visit by a forwarding agent.

An identity authentication system is composed of an
5 authentication card, a user terminal, and a card reader. Upon
insertion of the authentication card into the card reader, the
user terminal generates a random number, stores therein the
generated random number, and outputs the random number to the
authentication card. The authentication card generates
10 encrypted information by encrypting the received random number
using an identity certification key having been stored therein,
and outputs the generated encrypted information to the user
terminal. The user terminal decrypts the received encrypted
information using an identity authentication key having been
15 stored therein, and performs an authentication by judging whether
or not the decrypting result matches the stored random number.
